# Section: 5.5

# Objective: Review all Types of Factoring Problems (F.IF.8)

## Step I. Factor Out the Greatest Common Factor:

- Find the GCF.
- 2. Use the distributive property in reverse to "factor out" the GCF: Write the GCF outside a set of parentheses.

Inside the parentheses, write what is left when you *divide* the original terms by the GCF. **Note:** If the GCF is the same as one of the terms of the polynomial, there will be a 1 left inside

**Note:** If the GCF is the same as one of the terms of the polynomial, there will be a 1 left inside the parentheses.

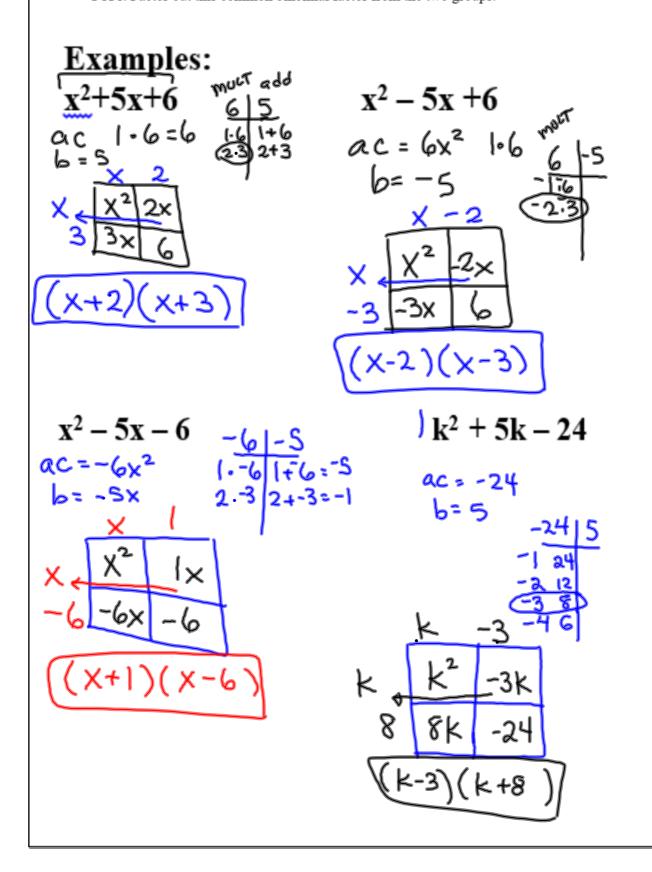

3. If leading coefficient is negative, factor out a common factor with a negative coefficient.

Examples: 
$$\frac{6b+6}{6(1b+1)}$$
  $\frac{4n^3-6n^2+8n}{4n^3-6n^2+8n}$   $\frac{4n^3-6n^2+8n}{6(1b+1)}$  GCF  $\frac{4n^3-6n^2+8n}{6(1b+1)}$   $\frac{6c}{6(1b+1)}$   $\frac{6c}{6(1b+1)}$   $\frac{2n(2n^2-3n+4)}{6(1b+1)}$ 

#### Step II. If the expression has 4 terms:

## Factoring by Grouping (4 Terms):

- 1. Factor out any common factors from all four terms first.
- 2. Look at the first two terms and the last two terms of the polynomial separately.
- Factor out the GCF from the first two terms, write a plus sign (or a minus sign if the GCF on the last two terms is negative), then factor out the GCF from the last two terms.
- 4. You should have the same thing left in both sets of parentheses after you take out the GCFs. Factor out this common binomial factor from the two groups.

## Factoring a Trinomial of the Form $ax^2 + bx + c$ by Grouping:

- 1. Always check for a GCF first! If there is a GCF, factor it out.
- 2. Multiply  $a \cdot c$ .
- 3. Find two numbers that multiply to your answer  $(a \cdot c)$  and add to b.
- 4. Rewrite the middle term bx as  $1st # \cdot x + 2nd # \cdot x$
- 5. Factor the resulting polynomial by grouping.
- 6. If there are no numbers that multiply to  $a \cdot c$  and add to b, the polynomial is prime.
